FIELD OF THE INVENTION

The present invention relates to the field of data communications. More particularly the invention describes a method of using codebook indexing to achieve high bit densities in
5 direct sequence CDMA spread spectrum communication systems.

BACKGROUND OF THE INVENTION

Direct Sequence Spread Spectrum (DSSS) techniques rely on the use of pseudo-noise carriers, also called spreading codes, spreading sequences, code sequences and chip
10 sequences, and a transmission bandwidth which is much wider than the minimum required to transmit the information. The transmitter spreads the information by modulating the information with a pseudo-noise spreading sequence. At the receiver, the information is despread to recover the base information. This despreading is accomplished by correlating the received, spread-modulated, signal with the spreading sequence used for the transmission.
15 DSSS is sometimes referred to by the shorthand name "direct spread."

The modulating signal, such as a pseudo-random spreading code signal, possesses a chip rate (analogous to carrier frequency) which is much larger than the data rate of the information signal. This characteristic is required for efficient spreading. Each state of the pseudo-random spreading sequence is referred to as a chip. The spreading sequence (chip
20 sequence) directly modulates each bit of the information signal, hence the name direct spread. Pseudo-randomness of the spreading signal is required in order to recover the original information signal. Since the spreading sequence is deterministic, it can be exactly duplicated

at the receiver in order to extract the information signal. If it were truly random, extraction of the information signal via correlation receiver would not be possible.

The spreading operation causes the signal power to be depleted uniformly across the spread bandwidth. Thus, the spread spectrum signal will appear buried in noise to any receiver without the despreading signal. Consequently, it is not only difficult to jam, but is also difficult to detect its presence in any bandwidth. Any undesired signal picked up during transmission is spread by the receiver in the same way that the transmitter spread the desired signal originally. In other words, the receiver spreads undesired signals picked up during transmission, while simultaneously despreading, or demodulating, the desired information signal. Processing gain is the term used to express this interference suppression in the overall transmit/receive operation. When viewed as a transmit/receive operation, the desired signal is spread-modulated twice, giving back the original signal, while in-band interference is spread-modulated once, and thereby depleted across the full spread bandwidth.

CDMA Direct Spread is an adaptation of conventional Direct Spread which accommodates multiple simultaneous access through the use of mutually orthogonal spreading codes. Mutually orthogonal means the cross correlation of any spreading code in the set is small (ideally zero). In an ideally orthogonal system, orthogonality not only means that there is no mixing of signals, but it also means that there is no interference between signals. In practice, the number of multiple access users cannot increase without bound because each user signal contributes a small multiple access interference component due to deviations from ideal. Since the receiver detection margin is not infinite, an eventual limit is reached.

SUMMARY OF THE INVENTION

A method for achieving high bit densities in a direct-sequence CDMA spread spectrum communication system. A table of orthogonal pseudo-noise codes is stored. This table is then partitioned into multiple codebooks. Then, each codebook is assigned to a user. The pseudo-noise codes contained within the codebooks are used to spread information signal.

5 Information signal for a first user is spread by a pseudo-noise code contained within the codebook assigned to the first user. Multiple bits of information signal may be sent at a time by using the location of the pseudo-noise code within the codebook such that the value of the information signal corresponds the location of the pseudo-noise code within the codebook. The information signal is then despread by using the same pseudo-noise code.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention is illustrated by way of example and not limitation in the figures of the accompanying drawings, in which like references indicate similar elements and in

15 which:

Figure 1(a) is a diagram showing a signal being spread.

Figure 1(b) is a diagram showing a spread signal with interference being demodulated into the original signal and noise.

Figure 2(a) is an exemplary prior art method of spreading signals.

Figure 2(b) is an exemplary method of spreading signals using codebook indexing.

Figure 3 is diagram of a pseudo-noise code table partitioned into multiple codebooks.

Figure 4 is a diagram showing a method of spreading signals for three users using the codebook indexing of the table of figure 3.

DETAILED DESCRIPTION OF THE INVENTION

355019-420050
The disclosed technique utilizes a previously unexploited grouping of orthogonal spreading codes into fixed codebooks for each user signal. By direct-spreading with a data dependent spreading code, where this spreading code is an indexed-member of a fixed-size
5 codebook, the information capacity of the transmitted signal is increased over conventional direct sequence spread spectrum techniques. This information capacity increase is achieved with virtually no change in transmit power or bandwidth. Implementation is relatively simple and does not alter the orthogonality properties at the receive since all codebook entries with a codebook, and among multiple codebooks, are derived from an orthogonal set. Codebook size
10 can be traded off for implementation resources, number of multiple access channels desired, and data rate differences between the multiple access channels.

By grouping a large orthogonal spreading code set into smaller codebooks, with each user signal assigned a unique codebook, multiple bits can be conveyed within each symbol period for each user signal. This grouping, together with the data-dependent index into the
15 codebook results in conveying an additional 'n' bits per symbol, where 'n' is the log-base-2 of the codebook size. Additionally, since each codebook is a distinct subset of the full orthogonal code set, multiple access capability is possible. Multiple user signals are each spread by a distinct set of orthogonal codes from the codebook assigned to a given user signal.

Figure 1(a) shows an example of what occurs to a signal when it is spread. Signal 100
20 is spread using a spreading sequence (not shown) into signal 101. As can be seen, the amplitude of the signal is decreased, while its bandwidth is expanded. By reducing the amplitude, the signal will appear indistinguishable from noise, and can only be recovered by a

receiver which processes the correct spreading sequence. Figure 1(b) shows the spread signal 101 and an interference signal 102 which has been picked up during transmission. When the spread modulated signal 101 is demodulated by using the original spreading sequence (not shown), the original signal 100 is recovered and the interference signal 102 is spread into
5 signal 103, thereby being reduced to noise.

Figure 2(a) is a diagram of an exemplary prior art method of spreading a signal. An information signal 210 is modulated, using known methods, by a pseudo-noise code 211. For each '1' in the information signal, the pseudo-noise code 211 is transmitted. Whereas for each '0' in the information signal, the inverse of the pseudo-noise code 211 is transmitted. Thus,
10 through such modulation, the signal is spread out for transmission into the transmitted signal 212. For example, if the information signal 210 consists of the bits '101' and the pseudo-noise code 211 is '01011010' then the transmitted signal 212 is '01011010 10100101 01011010.' This transmitted signal is created by '1' corresponding to the pseudo-noise code 211 ('01011010') and '0' corresponding to the inverse of the pseudo-noise code ('10100101').

15 Figure 2(b) is a diagram of an exemplary method of spreading a signal using codebook indexing. As described above, the information signal 210 is again modulated by a spreading signal to create a transmitted signal 214. However, in this case, instead of using a pseudo-noise code, codebook indexing is used. By using codebook indexing, multiple bits of information can be transmitted per pseudo-noise code instead of a single bit, as described
20 above. In codebook indexing, the position of the pseudo-noise code is used to encode multiple bits of information within the pseudo-noise code sent. Therefore, if two bits of information are to be sent per pseudo-noise code, a codebook with four entries is required because two bits of

information have four possible values, where the value ranges from zero to three. If the value of the information bits is 3 (the bits are '11'), then the fourth pseudo noise code, the one is position '11', contained within the codebook is used. In Figure 2(b), the same information signal 210 ('101') of Figure 2(a) is used. In this case, since a binary '101' equals a numeric 5, the sixth pseudo-noise code contained within the codebook, the one is position '101' is used. Assuming that this pseudo-noise code 211 '01011010,' then the transmitted signal is the pseudo-noise code of '01011010.'

Figure 3 is a diagram of an exemplary pseudo-noise table 300 where the table is broken into multiple codebooks. This table has 16 rows, row 0-15. User #1 (301) is assigned the first codebook 311. This codebook 311 contains the pseudo-noise codes contained within table positions 0-3, which are pseudo-noise codes A, B, C and D. User #2 (302) is assigned the second codebook 312. Codebook #2 (312) contains the pseudo-noise codes contained within table positions 4-7, which are pseudo-noise codes E, F, G and H. Finally, User #3 (303) is assigned the third codebook 313. Codebook #3 (313) contains pseudo-noise codes contained within table positions 8-15, which are pseudo noise codes I-P. In this example, codebook #1 (311) and codebook #2 (312) each contained four rows, thus, user #1 (301) and user #2 (302) are each assigned four rows. However, codebook #3 (313) contains eight rows, thus, user #3 (303) is assigned eight rows. As shown here, the number of rows contained within each codebook does not have to be equal, however, the number of rows contained within each codebook needs to be a power of 2 (i.e. 2, 4, 8, 16, 32, 64, etc.). Codebook #1 (311) contains four rows, therefore two bits of data may be sent per each pseudo-noise code. This is the case because to describe four rows, two bits are needed. Since codebook #3 (313)

contains eight rows, which requires three bits to describe all eight rows, three bits of data may be sent per each pseudo-noise code contained within codebook #3 (313).

Figure 4 shows an example of how to use the codebooks of the table of figure 3 to send multiple bits of data per each pseudo-noise code. If the information signal 401 is '10' and is for the first user, the pseudo-noise code contained within the first codebook at position '2' (or '10') within that codebook is used. This corresponds to pseudo-noise code C, therefore, the transmitted signal 403 is pseudo-noise code C. Similarly, if the information signal 404 is '10' and is for the second user, the pseudo-noise code contained within the second codebook at position '2' within the codebook is used. This corresponds to pseudo-noise code G, therefore, the transmitted signal 406 is pseudo-noise code G. Finally, in the case of signals for the third user, three bits of information can be sent per pseudo-noise code. Therefore, if the information signal 407 for user #3 is '010' the pseudo-noise code contained within the third codebook at position '2' is used. This corresponds to pseudo-noise code K, therefore, the transmitted signal 409 is pseudo-noise code K.

CLAIMS

What is claimed is:

1 1. A method for achieving high bit densities in a direct-sequence CDMA spread
2 spectrum communication system, the method comprising the steps of:
3 storing a table of orthogonal pseudo-noise codes;
4 partitioning the table of orthogonal pseudo-noise codes into at least one codebook;
5 assigning a first codebook to a first user;
6 spreading a first information signal for the first user with a first pseudo-noise code
7 contained within the first codebook.

1 2. The method of claim 1 wherein the location of the first pseudo-noise code
2 within the first codebook corresponds to the value of the first information signal for the first
3 user.

1 3. The method of claim 1 further comprising the step of:
2 spreading a second information signal for the first user with a second pseudo-noise
3 code contained within the first codebook.

1 4. The method of claim 3 wherein the location of the second pseudo-noise code
2 within the first codebook corresponds to the value of the second information signal for the
3 first user.

1 5. The method of claim 1 further comprising the steps of:
2 assigning a second codebook to a second user;
3 spreading a first information signal for the second user with a first pseudo-noise code
4 contained within the second codebook.

1 6. The method of claim 5 further comprising the step of:
2 spreading a second information signal for the second user with a second pseudo-noise
3 code contained within the second codebook.

1 7. The method of claim 6 wherein the location of the second pseudo-noise code
2 within the second codebook corresponds to the value of the second information signal for the
3 second user.

1 8. The method of claim 1 further comprising the step of:
2 despreading the first information signal for the first user with the first pseudo-noise
3 code within the first codebook.

1 9. The method of claim 8 wherein the location of the first pseudo-noise code
2 within the first codebook corresponds to the value of the first information signal.

1 10. The method of claim 1 wherein the partitioning the table of the orthogonal
2 pseudo-noise codes further comprises the step of:
3 partitioning the table into codebooks such that there are 2^n entries, where n is a
4 whole number.

1 11. The method of claim 1 wherein a single pseudo-noise code is capable of
2 transmitting multiple bits of information signal.

ABSTRACT

A method for achieving high bit densities in a direct-sequence CDMA spread spectrum communication system. A table of orthogonal pseudo-noise codes is stored. This table is then partitioned into multiple codebook. Then, the codebook is assigned to a user. The pseudo-noise code contained within the codebooks are used to spread information signal. Information signal for a first user is spread by a pseudo-noise code contained within the codebook assigned to the first user. Multiple bits of information signal may be sent at a time by using the location of the pseudo-noise code within the codebook such that the value of the information signal corresponds the location of the pseudo-noise code within the codebook. The information signal is then despread by using the same pseudo-noise code.

Title 37, Code of Federal Regulations, Section 1.56
Duty to Disclose Information Material to Patentability

(a) A patent by its very nature is affected with a public interest. The public interest is best served, and the most effective patent examination occurs when, at the time an application is being examined, the Office is aware of and evaluates the teachings of all information material to patentability. Each individual associated with the filing and prosecution of a patent application has a duty of candor and good faith in dealing with the Office, which includes a duty to disclose to the Office all information known to that individual to be material to patentability as defined in this section. The duty to disclose information exists with respect to each pending claim until the claim is cancelled or withdrawn from consideration, or the application becomes abandoned. Information material to the patentability of a claim that is cancelled or withdrawn from consideration need not be submitted if the information is not material to the patentability of any claim remaining under consideration in the application. There is no duty to submit information which is not material to the patentability of any existing claim. The duty to disclose all information known to be material to patentability is deemed to be satisfied if all information known to be material to patentability of any claim issued in a patent was cited by the Office or submitted to the Office in the manner prescribed by §§1.97(b)-(d) and 1.98. However, no patent will be granted on an application in connection with which fraud on the Office was practiced or attempted or the duty of disclosure was violated through bad faith or intentional misconduct. The Office encourages applicants to carefully examine:

- (1) Prior art cited in search reports of a foreign patent office in a counterpart application, and
- (2) The closest information over which individuals associated with the filing or prosecution of a patent application believe any pending claim patentably defines, to make sure that any material information contained therein is disclosed to the Office.

(b) Under this section, information is material to patentability when it is not cumulative to information already of record or being made of record in the application, and

- (1) It establishes, by itself or in combination with other information, a prima facie case of unpatentability of a claim; or
- (2) It refutes, or is inconsistent with, a position the applicant takes in:
 - (i) Opposing an argument of unpatentability relied on by the Office, or
 - (ii) Asserting an argument of patentability.

A prima facie case of unpatentability is established when the information compels a conclusion that a claim is unpatentable under the preponderance of evidence, burden-of-proof standard, giving each term in the claim its broadest reasonable construction consistent with the specification, and before any consideration is given to evidence which may be submitted in an attempt to establish a contrary conclusion of patentability.

(c) Individuals associated with the filing or prosecution of a patent application within the meaning of this section are:

- (1) Each inventor named in the application;
 - (2) Each attorney or agent who prepares or prosecutes the application; and
 - (3) Every other person who is substantively involved in the preparation or prosecution of the application and who is associated with the inventor, with the assignee or with anyone to whom there is an obligation to assign the application.
- (d) Individuals other than the attorney, agent or inventor may comply with this section by disclosing information to the attorney, agent, or inventor.
